19. THE MECHANISM OF ANTIBIOTIC ACTION OF BACT. PRODIGIOSUM
(Russian text) - Borju S. I. - MIKROBIOL. 1957, 26/4 (464-467)
Tables 1

The antibiotic activity of strains of Bact. prodigiosum is mainly due to the red pigment (prodigiosin). Unaltered prodigiosin can be detected in the cells of cultures susceptible to the antibiotic action of Bact. prodigiosum. The agar-microscopy method showed that prodigiosin penetrates into the living cells of the inhibited yeast and bacteria. At first the plasma and the inclusions are faintly stained. Subsequently prodigiosin accumulates in the cells, as brilliant red droplets and clumps or a diffuse staining of the whole cell. During this period cells are no longer able to reproduce but are still able to transform prodigiosin into a leuco compound.

Alkyl and arylchlorosilanes yield red-orange ppt on being reacted with tetramethyl diaminobenzophenone (I) in aniline. Organo-Si compd contg phenyl groups yield violet-red or cherry-red substances on walls of test tube after reaction with aluminum chloride and then benzene soln of I. Following qual reactions of alkyl and aryl deriv found: (1) Reaction with Aluminum chloride and benzene soln of I results in yellow-red ppt (2) Reaction with aluminum chloride and aniline soln of I results in ppt of different colors, so that various alkylalkoxysilanes can be distinguished from each other. Tetraethylsilane slowly dissolves aluminum chloride, forming a yellow soln which on addition of I in aniline results in red ppt. Qualitative method for detg tetraalkylsilanes is based on decolorization of Br on heating and one for detn of tetraphenylsilane on sepn of silicic acid upon heating with concd sulfuric acid.

Qualitative analysis of mixtures of alkoxy-silanes
with alcohols and silicon tetrachloride. A. P.
Kreshkov, V. A. Bork and V. T. Shevachikova
(*J. Anal. Chem.*, 1963, 9 [3], 166-169).—

The presence of silicon tetrachloride in tetramethoxy-
and tetraethoxy-silanes can be detected by (a)
reaction with HI to give I, (b) reaction with aniline
or with an aniline solution of tetramethylamino-
benzophenone to give a white or yellow ppt. sol. in
excess of reagent, (c) reaction with water to give
HCl, (d) reaction with $K_2Cr_2O_7$ and nitric acid in
parallel with a blank containing the esters only,
whereby the slower formation of a blue-violet
colour indicates the presence of $SiCl_4$, or (e) reaction
with ferric ferrihexathiocyanate, $Fe[Fe(SCN)_6]$, to
give decolorisation. The presence of methanol in
tetramethoxy-silane and ethanol in tetraethoxy-
silane can be detected by (a) reaction with Na to
give H_2 , (b) reaction with $Fe[Fe(SCN)_6]$, whereby a
red solution is obtained in presence of an alcohol, or
(c) reaction with $SiCl_4$ to give HCl. In presence of
 $SiCl_4$ only, the esters can be detected by their
reaction with borax and HCl or H_2SO_4 , followed by
a flame test. In presence of the alcohols only the
esters can be detected by the formation of SiO_2 on
being heated with HCl. G. S. SMITH

TITLE: Photocolorimetric Method for the Determination of the Phenoxy-Group in Organic Silicon Compounds (Fotokolorimetri-cheskiy metod opredeleniya fenoksigrupp v kremniyorgani-cheskikh soyedineniyakh).

PERIODICAL: Zhurnal Analiticheskoy Khimii, 1957, Vol. 12, Nr 6, pp. 764-764 (USSR)

ABSTRACT: The method of the determination of the phenoxy group in organic silicon compounds is based on the hydrolytic separation of the phenoxy-group as phenol and on the subsequent photocolorimetric determination of phenol as blue indophenol. Indophenol is formed by the action of chlorine and bromine water on phenolate in the presence of ammonium hydroxyde. The relative error on the determination of the phenoxy-group in tetraphenoxysilane amounts to 0,83%, in phenyl triphenoxy-silane to 0,27% with chlorine water (and 0,1%) with bromine water. There are 2 references, 1 of which is Slavic.

Photometric Determination of Trimethyl Chloro Silane in the Products of the Direct Synthesis of Silico-Organic Compounds (Fotometricheskiy metod opredeleniya trimetilkhlorosilana v produktakh pryamogo sinteza kremniyorganicheskikh soyedineniy)

PERIODICAL:

Nauchnyye doklady vysshey shkoly. Khimiya i khimicheskaya tekhnologiya, 1958, Nr 4, pp 727-730 (USSR)

ABSTRACT:

A photometric method was worked out for the determination of trimethyl chloro silane in mixtures of other methyl chloro silanes. This method is based on the interaction of trialkyl chloro silane with phosphorus anhydride and the developing ester of the phosphoric acid is converted into molybdenum blue complex. The conversion into molybdenum blue is carried out by means of SnCl_2 . For the construction of the calibration curve, standard benzene solutions of $(\text{CH}_3)_3\text{SiCl}$ with a content of 0.0364 g $(\text{CH}_3)_3\text{SiCl}/\text{ml}$ are used. Detailed working instructions are given. The method can be applied for the determination of

TITLE:

The Determination of Alcohol and Phenol Admixtures in Organosilicon Compounds Containing Ethoxy, Methoxy, and Phenoxy Groups (Opredeleniye primesi spirtov i fenolov v krem-niyorganicheskikh soyedineniyakh, soderzhashchikh etoksi-, metoksi- i fenoksi-gruppy)

PERIODICAL:

Zhurnal analiticheskoy khimii, 1958, Vol. 13, Nr 4, pp. 499-500 (USSR)

ABSTRACT:

The authors of the present paper used for the photometric determination of alcohols the reaction described in literature which is based on the capability of the alcohols to dissolve $Fe[Fe(SCN)_6]$ under the formation of a red color (Ref 1). Besides, a method was suggested for the determination of alcohol admixtures. It is based on the capability of the alcohols to dissolve methyl violet dye under the formation of a violet colored solution: organosilicon compounds containing alkoxy groups do not dissolve this reagent. $Fe[Fe(SCN)_6]$ was used in form of a dry powder. Its production was carried out from potassium thiocyanate and Ferrichloride in absolute methanol.

Card 1/3

The Determination of Alcohol and Phenol Admixtures in Organosilicon Compounds Containing Ethoxy, Methoxy, and Phenoxy Groups

SOV/75-13-4-25/29

Calibration curves for the determination of ethanol with $\text{Fe} [\text{Fe}(\text{SCN})_6]$ and with methyl violet were plotted. The photometric measurements were carried out by means of a Pulfrich photometer. The absolute error of the determination of the content of ethanol in tetraethoxy silane or other organosilicon compounds containing ethoxy groups amounts to 0,01% - 0,02%, the relative error to about 1%. This method makes possible the determination of amounts of up to 1,5% alcohol by means of $\text{Fe} [\text{Fe}(\text{SCN})_6]$ and of 1,4 - 5% alcohol when using methyl violet.

The determination with methyl violet was carried out by the authors also for methanol. Phenol can be determined in organosilicon compounds from an aqueous extraction which can be separated from the phenoxy silanes and other organosilicon compounds insoluble in water (Ref 2). The determination of phenol is carried out photometrically on the basis of the coloration with Ferrichloride or with ammoniacal copper salt. The measurements were carried out by means of a Pulfrich photometer. Also for these determinations calibration curves were plotted which are mentioned in the paper. The smallest amount of phenol

Card 2/3

The Determination of Alcohol and Phenol Admixtures in Organosilicon Compounds Containing Ethoxy, Methoxy, and Phenoxy Groups

SOV/75-13-4-25/29

which can be traced in the determination with Ferrichloride is 0,05%, and in the determination of ammoniacal copper salt solution it is 0,015%. The relative error in the determination in either case amounts to 0,7 - 1,4%. The plotting of the calibration curves and the carrying out of the determinations are described in detail. There are 3 figures and 2 references, 2 of which are Soviet.

TITLE: Successes in the Field of Analysis of Organosilicon Compounds
(Uspekhi v oblasti analiza kremniyorganicheskikh soyedineniy)

PERIODICAL: Uspekhi khimii, 1959, Vol 28, Nr 5, pp 576 - 604 (USSR)

ABSTRACT: The publication data on the analysis of organosilicon compounds were generalized in the present paper. Organosilicon compounds are characterized by specific properties which differ from the corresponding hydrocarbons and their analogues to a considerable extent. These properties do not permit to employ the methods used in the analysis of organic substances without corresponding modifications. Sometimes it is necessary to develop completely new methods. In this connection also a certain similarity between the individual organosilicon compounds and organic compounds is to be taken into account. The comparison of physical constants of organosilicon compounds and the constants of the corresponding carbons is of great theoretical and practical importance. The comparison of refractive indices and surface tension permits the conclusion that in this case more complicated relations are concerned than in the case of a comparison of densities with boiling points of the same compounds. Recent-

Card 1/4

Successes in the Field of Analysis of Organosilicon Compounds SOV/74-28-5-4/7

ly new methods of quantitative determinations of organosilicon compounds as well as of various substances produced on the basis of them were worked out. It was the first time that general qualitative reactions with organosilicon compounds as well as reactions with individual classes and representatives of these compounds were discovered. (Refs 3-16). Recently many papers by Soviet and foreign research workers dealing with quantitative analyses were published; the subject of the mentioned papers is both elementary analysis of organosilicon compounds and the detection of the functional groups they contain. The decomposition of these compounds - silicic acid is formed in this connection - is brought about by various methods. These methods may be divided into 4 principal groups: A) Methods on the basis of combustion (Refs 17-31); B) Methods of wet oxidation (Refs 10, 23, 33-44); C) Methods on the basis of amalgamation (Refs 10, 20, 45-49); D) Methods on the basis of hydrolytic decomposition (Refs 10, 40, 50-64). The development of the elementary method took the way of completion of all mentioned methods. For determining the functional groups methods are employed that were suggested for the determination of the following types of

Card 2/4

Successes in the Field of Analysis of Organosilicon Compounds SOV/74-28-5-4/7

groups: A) alkoxy- and aroxy groups (Refs 4, 65-68); B) hydroxyl groups (Refs 10, 69-78); hydrogen bound with silicon and Si-Si bonds (Refs 10, 40, 79-87); D) acetyl groups (Refs 23, 24, 88-90); E) double and treble bonds (Refs 91, 92); F) phenyl groups directly bound to silicon atoms (Ref 93). The physico-chemical and physical methods of analysis are: 1) photocolometric analysis (Refs 10, 16, 45, 75, 94-103); 2) Molecular spectrum analysis (Refs 10, 104-130); 3) thermographical method (Refs 131-133); 4) titration in anhydrous media (Refs 16, 68); 5) polarographical analysis (Ref 134). Furthermore, several papers deal with the analysis of technical products: 1) analysis of ceramic substances on organosilicon basis (Refs 135, 136); 2) analysis of polysiloxane liquids (Refs 32, 65, 137-138); 3) analysis of several other technical products obtained on organosilicon basis (Refs 139-142); 4) analysis of several mixtures obtained as a result of the synthesis or the decomposition of organosilicon compounds (Refs 143-146). The production control of organosilicon compounds is described by several papers: 1) production control of ethyl- and phenylethoxy siloxanes (Ref 93); 2) control of the direct synthesis of methyl-, ethyl- and phenyl-

Card 3/4

Successes in the Field of Analysis of Organosilicon
Compounds

SOV/74-28-5-4/7

chlorosiloxanes (Refs 51, 93, 108); 3) control of hydrolysis and the condensation processes in the production of polymeric organosilicon compounds (Ref 93); 4) analysis of organosilicon polymers (liquids and varnishes) (Refs 21, 22, 93). The further development of the analysis of organosilicon compounds is the natural consequence of the demands made by production. The existing control methods are no more sufficient for the modern requirements. They are in the first line too slow and in the case of several processes of production there are no satisfactory methods at all. It is impossible to prefer one of the mentioned methods. Only a combination of chemical, physical and physico-chemical methods on the basis of the use of all technical means, gathered by the carrying out of analytical chemistry through several years, may correspond to the requirements made to the methods of analysis. There are 146 references, 84 of which are Soviet.

TITLE: The Preparation of Corundum Base Acid-Resistant Materials by the Addition of Silicon-Organic Polymers
(polucheniye kislotoupornykh materialov na osnove korunda s dobavkoy kremniyorganicheskikh polimerov)

PERIODICAL: Zhurnal prikladnoy khimii, 1959, Vol 32, Nr 4, pp 750-756 (USSR)

ABSTRACT: Acid-resistant products may be manufactured from white electric corundum with the addition of a silicon-organic polymer, i.e., ethylsilicate 40, which has been hydrolyzed in a water-alcohol solution to a SiO₂ content of 21.9%. During pyrolysis the organic part of the compound volatilizes and the silica polymer coats the grains of the principal material [Ref 1, 2]. Electric corundum of the following types is used in the experiments: 100, 160, 320, and the micropowder M-7. The acid-resistance is tested by heating to 300°C and cooling in sulfuric acid in three cycles of 72 hours each. The samples burnt at 1,250°C have the highest mechanical resistance at a SiO₂ content of 3%. The temperature of 1,250°C is too low for such high-melting materials as electric corundum. At 1,600°C, shrinking of the samples is observed which reaches the highest

Card 1/2

The Preparation of Corundum Base Acid-Resistant Materials by the
Addition of Silicon-Organic Polymers

value in the fine powder M-7. The acid-resistance is the highest in samples burnt at 1,600°C (Table 7). The lowest solubility have the samples manufactured on the base of coarsely grained corundum. Dense acid-resistant materials without filtering properties are obtained at SiO₂ additions of 1.5 g/m² to 5-7 g/m². There are 8 tables, 6 graphs, and 4 Soviet references.

TITLE: Color Reactions for Organosilicon Compounds and Their Use for Photometric Analysis

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Khimiya i khimicheskaya tekhnologiya, 1960, Vol. 3, No. 3, pp. 410 - 415

TEXT: The authors report on color reactions developed by them, as well as photometric methods for determining organosilicon compounds. The latter methods are based on the application of the reactions mentioned. This study was mainly conducted because the analysis methods of organosilicon compounds still cannot keep up with their synthesis. The usual methods for organic compounds are therefore difficult to apply. The following peculiarities of organosilicon compounds were utilized for the analysis methods described here: 1) their tendency towards hydrolysis, accompanied by intermolecular condensation; 2) the reactivity of some

Card 1/3

highly mobile atoms of the functional groups combined with silicon (Hal, -OR, H, -NH₂, -SR, -CN, -SCN); 3) the great stability of the C-Si bond. At the same time use was made of a certain similarity of the organosilicon compounds with their organic analogs. In conclusion the authors describe the following qualitative reactions elaborated by them: for amino silane, phenoxysilane, hexa-alkyldisiloxane as well as for HSiCl₃ and SiCl₄. They also elaborated photometric methods for the following organosilicon compounds and their mixtures: a) phenoxy- and ethoxy groups in organosilicon compounds; b) admixtures of ethanol and methanol to methoxy- and ethoxy silanes; c) phenol admixture to phenoxy-silanes; d) for trimethylchlorosilane in the presence of other methyl-chlorosilanes; e) for trichlorosilane and f) for admixtures of SiCl₄ in alkoxysilanes. These photometric methods warrant quick analyses and no reagents difficult to obtain or expensive are necessary. There are 22 Soviet references.

TITLE: Quantitative analysis of products of direct synthesis of alkyl chloro silanes

PERIODICAL: Zavodskaya laboratoriya, v. 27, no. 2, 1961, 147-149

TEXT: A satisfactory method has so far not been elaborated for the production control of alkyl chloro silanes and their derivatives. In the present case, a method is described which permits a quick and simple determination of the individual components in the mixture of alkyl chloro silanes. The determination of methyl trichloro silane is based on the formation of solid polymer compounds after hydrolytic cleavage and subsequent condensation of the resulting methyl silanetriol. Under these conditions, the other methyl chloro silanes form liquid linear polymers so that the amount of solid polymer can be quantitatively determined by gravimetry or nephelometry. The determination of hydrogen-containing methyl chloro silanes is based on an oxidation of the $\equiv\text{SiH}$ bond with permanganate. SiCl_4 is determined by means of an aqueous solution of

Page 1/3

Quantitative analysis of products ...

S/032/61/027/002/004/026
B134/B206

molybdate, since silicon molybdenum heteropoly acid forms thereby which can be photometrically determined owing to its blue color. The other compounds showing a $\equiv\text{Si}-\text{C}\equiv$ bond do not react with ammonium molybdate. Trimethyl chloro silane is determined by a method previously described (Ref. 9), while the content of dimethyl dichloro silane in the mixture can be calculated from the difference. From the working technique described it can be seen that for the nephelometric determination of methyl trichloro silane in the mixture by means of an ФЭК-М (FEK-M) instrument, a calibration curve must be plotted, since the degree of turbidity depends on the way the mixture was prepared. Up to 10% dimethyl dichloro silane and up to 5% trimethyl chloro silane do not disturb the determination. The content of methyl trichloro silane according to the gravimetric method is calculated by the equation

$$\text{CH}_3\text{SiCl}_3 = (\text{aSiO}_2 + 2.33)/0.16 \quad (\text{aSiO}_2 = \text{quantity of SiO}_2 \text{ weighed after igniting.})$$

For the determination of SiCl_4 , a somewhat modified method (Ref. 10) is applied to determine the ortho-silicic acid ester. The analytical results show that SiCl_4 can be determined by this method in

TITLE: Determination of $\equiv \text{SiH}$ bonds containing organosilicon compounds by amperometric titration in ethanol-benzene solution

PERIODICAL: Zhurnal analyticheskoy khimii, v.17, no. 3, 1962, 359-361

TEXT: A critical review includes previous works by the author using non-aqueous solutions. The new method is based on the reaction

carried out by titration of the sample with mercuric chloride, and using LiCl dissolved in a mixture of methanol and benzene. Procedure: 0.07-0.12 g of the sample, a hydrogen-containing organosilicon compound are dissolved in benzol and diluted to 25 ml. 0.5-2 ml of this solution is made up to 25 ml with a benzene-methanol mixture (1:1), containing 0.3 mol/l LiCl. The solution is mixed with a glass stirrer and a quantity of metallic mercury is introduced together with a mercury electrode. The polarographic wave was measured at $E = -0.8\text{V}$. After this, a solution of HgCl_2 in a $\text{CH}_3\text{OH}/\text{C}_6\text{H}_6$ (1:1) mixture containing 3 g HgCl_2 in 100 ml is added from a microburet, and the height of the wave measured after the addition of each portion of HgCl_2 solution. The results are plotted on a graph of the volume of added HgCl_2 vs. the height of the wave. The diagrams show the

Card 1/2

Determination of = SiH bonds containing...

S/075/62/017/003/004/004
I017/I027

volume of HgCl_2 necessary to obtain the end point. Typical diagrams show determinations of synthetic and industrial mixtures. The results of three series of experiments show that the method permits titrations of alkylchlorosilanes containing $\equiv \text{SiH}$ bonds; successful determinations are carried out with 0.001 g $\text{CH}_3\text{SiHCl}_2$ containing 1.2×10^{-5} g hydrogen (with silicon). The determination of hydrogen bonded with silicon in alkylchlorosilanes ($\text{CH}_3\text{SiHCl}_2 + \text{CH}_3\text{C}_6\text{H}_5\text{SiCl}_2$) is successful for the range 0.1–0.008%. The determination of ethoxysilanes ($(\text{C}_2\text{H}_5\text{O})_3\text{SiH}$ and $(\text{C}_2\text{H}_5\text{O}_4)\text{Si}$) by this method gives good results for a very wide range of concentrations of the compound being determined; the % error varies from $\pm 0.01 - 0.60$ (absolute). There are 3 figures and 1 table.

TITLE: Quantitative determination of hydrogen-containing organo-silicon compounds

PERIODICAL: Zavodskaya laboratoriya, v. 28, no. 2, 1962, 151 - 154

TEXT: Two methods are described which are based on the formation of Hg_2Cl_2 formed by reaction of $HgCl_2$ with hydrogen bound to Si. In the phototurbidimetric method, the optical density of the Hg_2Cl_2 suspension is determined by an ФЭК-М (FEK-M) photocolormeter with yellow light filter. Acetone, methyl-ethyl ketone, or their mixtures with benzene were used as solvents. All solvents produced proportional dependence of the optical density on the concentration of the hydrogen-containing organosilicon compounds. 75% benzene + 25% methyl-ethyl ketone was found to be optimum. When determining hydrogen in $CH_3C_6H_5SiHCl_2$, the presence of phenyl-methyl dichloro silane reduces the optical density. A special calibration scale

Card 1/3

Quantitative determination of...

S/032/62/028/002/003/037
B101/B110

must, therefore, be plotted for determining the $\text{CH}_3\text{C}_6\text{H}_5\text{SiHCl}$ content in phenyl-methyl dichloro silane. The optimum weighed portion of hydrogen-containing organosilicon compound is determined by a preliminary test. The analysis is conducted by comparing the optical densities of two specimens, a standard solution of the hydrogen-containing compound (0.03 g in 50 ml of benzene) being added to one specimen. HgCl_2 (2 g in 100 ml of benzene (75%) + methyl-ethyl ketone) is added to both specimens, and the optical density is measured after 1 hr. This method permits the determination of $5 \cdot 10^{-5}\%$ of Si-bound hydrogen. The maximum relative error is 10%. The standard solution may be used a month. For the gravimetric method, the compound containing an SiH bond is dissolved in an anhydrous solvent, mixed with 2% HgCl_2 solution, and after 1 hr the Hg_2Cl_2 precipitate is filtered off through a glass filter, rinsed with the solvent, dried for 10 min at $90 - 100^\circ\text{C}$, and then weighed. This method permits the determination of $2 \cdot 10^{-3}\%$ of Si-bound hydrogen. There are 4 tables and 6 references: 3 Soviet and 3 non-Soviet. Practical handbook on analysis of monomeric and polymeric silicones (Prakticheskoye rukovodstvo po analizu monomernykh i polimernykh kremniyorganicheskikh soyedineniy), Moscow, Goskhimizdat, 1962, 544 p. illus., biblio., index. Errata slip inserted. 6,000 copies printed.

TOPIC TAGS: monomeric silicone, polymeric silicone, silicon, carbon, quality control, lacquer, enamel

PURPOSE AND COVERAGE: This book is a handbook on analysis of monomeric and polymeric silicone compounds. It gives the fundamentals of the theory and modern chemical, physical, and physical-chemical methods of analyzing silicon compounds, methods of determining their physical constants and structure, methods of analyzing the basic chemical products used in their production, and also the methods used in experimental and industrial facilities for quality control. The book is intended for engineers, technicians, and researchers of research and plant laboratories and also for students and graduate students in the field of elemento-organic compounds.

TITLE: Methods for analyzing organosilica compounds containing silica-bonded hydrogen

SOURCE: AN SSSR. Komissiya po analiticheskoy khimii. Trudy. v.13, 1963.
Organicheskiy analiz. 148-156

TOPIC TAGS: hydrogen, silica, phototurbometric method, gravimetric method, photolorimetry, permanganate method, acetic acid, HgCl₂, acetone, methylethylketone

ABSTRACT: Several new methods for the determination of silica-bonded hydrogen atoms in organosilica compounds have been developed. These methods are:
(i) Phototurbidimetric method - based on the reaction of SiH-bond with HgCl₂ in non-aqueous solvents such as acetic acid, acetone, methylethylketone, ethylacetate and butylacetate and also methylethylketone-benzene, and ethylacetate-benzene mixtures; (ii) Gravimetric method - based on the weighing of calomal precipitate obtained by reacting SiH bond with HgCl₂ in benzene-acetone solvent. This method is very simple and fairly accurate;

Card 1/2

-L 13322-63

ACCESSION NR: AT3002343

(iii) Photocolorimetric method - based on the oxidation of SiH bond with KMnO_4 . The color intensity decreases with an increase of concentration of hydrogen containing compounds. The method can be applied in the determination of hydrogen containing impurities up to 30%; (iv) Permanganate method - this method is based on the oxidation of SiH bond with KMnO_4 . The mixture is dissolved in glacial acetic acid and titrated with standard 0.05 N KMnO_4 strongly acidified with H_2SO_4 . Orig. art. has: 5 tables and 3 figures.

TITLE: Basic problems in designing autodynes

SOURCE: Meres es automatika, v. 13, no. 1, 1965, 3-6

TOPIC TAGS: radio receiver, radio equipment

ABSTRACT: Some considerations involved in the designing of autodynes were discussed based on the authors' experience in this field. Formulae were derived for the calculation of the maximum output of direct-current units, single-armature converters, and autodynes proper. Other design considerations discussed include the number of poles for the desired output, the number of phases, and the tension ratio. Some specific parameters for various output ranges in the medium-output class were presented. Orig. art. has: 3 figures, 17 formulas, and 2 tables. [JPRS]

TITLE: Scale resistance of titanium-carbide-based sintered hard alloys.

SOURCE: Vsesoyuznyy nauchno-issledovatel'skiy institut tverdykh splavov. Sbornik trudov. no.2. Moscow, 1960. Tverdyye splavy. pp.148-157.

TEXT: Following a brief survey of the current state of knowledge on TiC-based and Co-cemented sintered alloys (13 all-Western references), the results of 100-hour tests up to 1200°C with varying amounts of NbC, WC, and Co are reported. The preparation of the compound mixtures is described and summarized in a full-page table. According to X-ray analysis, the crystalline lattice of TiC has a period $a=4.32 \text{ \AA}$, that of NbC $a=4.46 \text{ \AA}$ (one phase each only). X-ray analysis of the compound carbide mixture (87% TiC, 13% NbC) manifested the presence of a single solid-solution phase of cubic structure with $a=4.35 \pm 0.03 \text{ \AA}$. Microhardness: NbC 1820 kg/mm², TiC //Abstracter's note: Should probably read TiC-NbC // 2470 kg/mm². The carbide and Co powders were ground and mixed in alcohol in ball mills for 5 days. 5x5x40 mm specimens were pressed at 1000 kg/mm² pressure and sintered in tubular graphite electric furnaces in a H-atmosphere at 1450 to 1560°C. TiC-NbC-Co alloys: In tests at 1000° with a constant 25% Co content,

an increase in NbC from 0 to 10% improves the scale resistance steadily (weight increase drops from 5 to 1 g/m²·hr); no appreciable improvement appears beyond 10% NbC. However, scale-resistance tests from 900 to 1200°C show an optimal value of 15% NbC, especially at the higher temperatures. Tests with a constant NbC and varying Co contents at 1000°C show that a 25% Co content is optimal for scale resistance. A slight advantage is noted in alloys obtained by mixing the compound TiC-NbC powder with Co powder as against alloys made by mixing the separate simple TiC and NbC powders with Co powder of the same % composition. The optimal alloy contains 15% NbC, 25% Co, 60% TiC, with a scale-resistance limit of 1100°C. TiC-WC-Co alloys: Scale resistance was found to improve with increased WC content (e.g., TiC/WC = 65/35). An increasing Co content (from 5 to 25%) improves the scale resistance of the latter alloy, but less so for alloys with smaller WC contents. Rapid oxidation occurs at 1100°C. Optimal composition: 30% WC, 15-20% Co, remainder TiC; scale-resistance limit 900°C. TiC-WC-NbC-Co alloy: Alloys with 10 and 15% NbC and 10 to 20% Co were more scale-resistant than TiC-WC-Co, but less than TiC-NbC-Co. There are 6 figures, 2 tables, and 13 references (8 English-language and 5 German).

ASSOCIATION: None given.
